

In radians
 $a = r\theta$
 In degrees

$\alpha =$ central angle in degrees

$$a = \frac{2\pi r \alpha}{360}$$

$\theta = 1$ full revolution in radians
 $a =$ circumference $= 2\pi r$

$$2\pi r = r\theta$$

$$\theta = 1 \text{ rev} = 2\pi \text{ radians}$$

$$\div 2 \quad \frac{2\pi \text{ rad}}{\pi \text{ rad}} = 1 \text{ rev} = 360^\circ$$

$$\div 2 \quad \frac{\pi \text{ rad}}{\frac{\pi}{2} \text{ rad}} = \frac{1}{2} \text{ rev} = 180^\circ$$

$$\div 2 \quad \frac{\frac{\pi}{2} \text{ rad}}{\frac{\pi}{4} \text{ rad}} = \frac{1}{4} \text{ rev} = 90^\circ$$

Why radians? formulas will be simpler

Eq $a = r\theta$ vs $a = \frac{2\pi r \alpha}{360}$

Recall $\pi \text{ rad} = 180^\circ$

Example convert 2 rad to degrees.

$$\div \pi \quad 1 \text{ rad} = \left(\frac{180}{\pi}\right)^\circ$$

$$\times 2 \quad 2 \text{ rad} = \left(\frac{360}{\pi}\right)^\circ \quad \checkmark$$

Example convert 120° to radians.

$$\pi \text{ rad} = 180^\circ$$

$$\div 180 \quad \frac{\pi}{180} \text{ rad} = 1^\circ$$

$$\times 120 \quad \frac{120\pi}{180} \text{ rad} = 120^\circ$$

$$\frac{2\pi}{3} = \frac{6 \times 2\pi}{6 \times 3} \text{ rad} = 120^\circ$$
